Abstract. Heat pipes are among the most promising technologies for space radiator systems. The paper reports further evaluation of potential heat pipe fluids in the intermediate temperature range of 400 to 700 K in continuation of two recent reports. More thermo-physical property data are examined. Organic, inorganic and elemental substances are considered. The evaluation of surface tension and other fluid properties are examined. Halides are evaluated as potential heat pipe fluids. Reliable data are not available for all fluids and further database development is necessary. Many of the fluids considered are promising candidates as heat pipe fluids. Water is promising as a heat pipe fluid up to 500-550 K. Life test data for thermo-chemical compatibility are almost non-existent.

# Heat Pipe Technologies - Current Status

- Below 400 K
- Ex.: Commercial and space electronics applications - mature technology
- High temperature alkali metal heat pipes -Above 700 K

technologies exist

- Intermediate Temperature Heat Pipe Technologies Temperature range 400 - 700 K: Defined as
- Far less developed

Glenn Research Center at Lewis Field

# Intermediate Temperature Heat Pipes

# Current Technology Development Approaches

- Augment the upper operational temperature limit of the ambient temperature heat pipe technology-Ex: Water heat pipes
- Develop new technologies for the intermediate temperature heat pipes

## New in the Current Work

### Recent Reports

- Anderson et al. (2004)
- Devarakonda and Olminsky (2004)

### Present Work

- Better data
- Better property estimates
- More fluids

Glenn Research Center at Lewis Field

# Intermediate Temperature Heat Pipe Fluids

## Important characteristics to look for

- Maximum operational temperature should be at least 100 K below the critical temperature
- Must be in fluid phase, i.e., melting point below the operational temperature

characteristics. Some elements (Ex. Sulfur and A number of halides seems to have the requisite lodine) are also potential heat pipe fluids.

Glenn Research Center at Lewis Field

## Properties - Overall View

- Reliable data are not available for many materials
- Estimates are made if a given property is known for one material in a family.
- If a method is known to work to estimate properties of a family of fluids, that method is used for other families too, based on the known data.

In some cases no data are known. Ex.: The following halides could not be evaluated

- BCl<sub>3</sub>, BBr<sub>3</sub>, Bl<sub>3</sub>
- SiCl<sub>4</sub>, SiBr<sub>4</sub>, Sil<sub>4</sub>

Possible heat pipe fluids: Halides of AI, Bi, Ga, Sb, Sn, and Ti

## Surface Tension Estimation

Reid, Prausnitz and Poling (1987) recommendation: properties and normal boiling point are known Based on corresponding states equation- critical First step: Calculate Q

$$Q = 0.1196 \left[ 1 + \frac{T_{Boil}}{T_{Critical}} \ln(P_{Critical}) \right]$$

$$1 - \frac{T_{Boil}}{T_{Critical}}$$

Glenn Research Center at Lewis Field

## Surface Tension Estimation

Second step: Calculate surface tension, o

$$\sigma = Q \bigg( \frac{P_{Critical}}{Bar} \bigg)^{\frac{2}{3}} \bigg( \frac{T_{Critical}}{K} \bigg)^{\frac{1}{3}} \bigg( 1 - \frac{K}{T_{Critical}} \bigg)^{\frac{11}{9}} \frac{10^{-3}}{m} \frac{N}{m}$$

Better estimation is given by

(authors):

$$\sigma_{\text{Halide}} = \frac{2}{3}\sigma$$

Temperature (K) 400 450

### Vapor Pressure

- Water heat pipe technologies are widely available. Hence, water is benchmarked as the high end
- Cesium vapor pressure is too low in this temperature range. Hence, it is considered as the low end.

The vapor pressures of all the fluids evaluated fall within this range.

### Figure of Merit

Definition of Figure of Merit (In "Liquid Transport Factor") Heat Pipe literature, also called, "Merit Number",

whose values are desired to be higher and those desired higher the value of the Merit properties in the numerator Number, the better the fluid is thought to be for a heat denominator, Hence, the Merit Number, M, has those to be lower in the

> $M = \rho_{\rm L} \cdot \sigma \cdot \lambda$ H

### Summary

- Halides and some elemental materials evaluated for potential Intermediate Temperature Heat Pipes, 400 to 700 K.
- Properties estimated from known data wherever possible
- Not all possible fluids could be evaluated due to paucity of data
- Some materials identified as potential heat pipe fluids and for thermo-chemical compatibility testing with metals
